Sir:

**CLAIM FOR PRIORITY**

Under the provisions of 35 U.S.C. § 119, Applicants hereby claim the benefit of the filing date of Australian Patent Application No. 78277/01, filed October 8, 2001, for the above-identified U.S. patent application.

In support of this claim for priority, enclosed is one certified copy of the priority application.

Respectfully submitted,

FINNEGAN, HENDERSON, FARABOW,  
GARRETT & DUNNER, L.L.P.

**Title:**

Methods and Apparatus for Developing Investments

**Field of the Invention:**

The present invention relates to methods and associated apparatus for  
5 developing investments. The invention has been developed primarily for use by  
investors, for example superannuation funds, pension funds, investment managers,  
mutual funds, investment companies, insurance companies, etc, as an aid in  
formulating an investment portfolio in tradable financial investments such as financial  
instruments, securities, equities, shares, futures, options, warrants, bonds,  
10 promissory notes, etc and will be described with reference to this application.  
Additionally the invention can be applied to a range of investment styles, such as  
value, growth, index, quantitative, or passive. However it will be appreciated by  
those skilled in the art that the invention is not limited to this particular field of use.

**Discussion of the Prior Art:**

15 Investors generally have the choice of investing funds either domestically,  
internationally or in a combination of the two. For example, for Australian  
superannuation funds the current average ratio of domestic equity investments to  
international equity investments is approximately 60:40. A prior art technique for  
benchmarking the domestic component of an investment is to compare its  
20 performance to that of a domestic benchmark index, for example an applicable  
Australian index is the ASX/S&P 200 or 300. Similarly, the international component  
may be benchmarked against a suitable international index excluding the domestic  
component thereof, for example the MSCI World Index ex Australia.

In many countries the domestic benchmark is dominated by a small number  
25 of local companies. For example, in Australia shares in News Corporation represent  
approximately 10% of the domestic equity market capitalisation. Hence the 60:40  
ratio mentioned above would result in a weighting of News Corporation shares of 6%

which is out of step with the weight of the global media industry in the world economy. In other words, this may be considered to be an imbalanced exposure.

Additionally, some industries dominate a domestic market whereas others are under represented. For example, the Australian equities market is comparatively  
5 over represented in resource based stocks and under represented in industries such as pharmaceuticals and technology.

It is recognised that country or regional influences on equity market returns have been slowly reducing, whereas factors relating to industry groups are typically having an increasing influence on equity markets. This reflects the globalisation of at  
10 least some industries. While international investments give rise to diversification benefits, many investors prefer to favour investing within a specific domestic economy, often to support their local industries.

Any discussion of the prior art throughout the specification should in no way be considered as an admission that such prior art is widely known or forms part of  
15 common general knowledge in the field.

**Object of the Invention:**

It is an object of the present invention to overcome or ameliorate at least one of the disadvantages of the prior art, or to provide a useful alternative.

**Summary of the Invention:**

20 In accordance with a first aspect of the present invention there is provided a method for determining weightings of an investment portfolio selected from a range of domestic and international financial investments, said method including the steps of:

a) dividing said range of domestic and international financial investments into  
25 a plurality of industry based groups;

b) selecting one of said industry based groups;

c) determining a required\_industry\_weighting for said selected industry based group;

d) determining an available\_domestic\_weighting for said selected industry based group;

e) determining a mixture of financial investments within said selected industry based group, whereby said mixture consists of:

5 e1) exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting; otherwise

e2) domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international financial investments  
10 having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting; and

f) repeating steps b) to e) until mixtures of financial investments for all of said industry based groups have been determined, thereby forming the weighting of said investment portfolio.

15 In one embodiment the domestic equity investments in step e1 have a weighting substantially equal to said required\_industry\_weighting.

In accordance with a second aspect of the present invention there is provided a method of determining a mixture of financial investments within a pre-selected industry based group, said method including:

20 a) determining a required\_industry\_weighting for said pre-selected industry based group;

b) determining an available\_domestic\_weighting for said pre-selected industry based group;

c) determining the mixture of financial investments within said pre-selected  
25 industry based group, whereby said mixture consists of:

c1) exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting; otherwise,

c2) domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international equity investments having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting.

5 In accordance with a third aspect of the present invention there is provided a method for determining weightings of an investment portfolio selected from a range of domestic and international financial investments, said method including the steps of:

a) dividing said range of domestic and international financial investments into  
10 a plurality of groups;

b) selecting one of said groups;

c) determining a required\_industry\_weighting for said selected group based upon investor criteria;

d) determining an available\_domestic\_weighting for said selected group  
15 based upon statistical information;

e) determining a mixture of financial investments within said selected group, whereby said mixture consists of:

e1) exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting;  
20 otherwise,

e2) domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international financial investments having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting; and

25 f) repeating steps b) to e) until mixtures of financial investments for all of said groups have been determined, thereby forming the weighting of said investment portfolio.

In one embodiment the statistical information is a domestic benchmark or index and the investor criteria is based upon an international benchmark or index.

In accordance with a fourth aspect of the present invention there is provided a method of determining a spread of investments across  $i$  groups of financial

5 investments, each of said groups including domestic financial investments and international financial investments, said method including the following steps for each of the  $i$  groups:

a) defining a desired weight ( $W^G_i$ );

b) determining the weight of domestic financial investments ( $W^D_i$ );

10 c) calculating a domestic weight ( $w^d_i$ ) within the spread of investments and a international weight ( $w^p_i$ ) within the spread of investments as follows:

$$w^d_i = W^G_i \quad \text{if } Adequate(W^G_i, W^D_i) = True$$

or

$$w^d_i = W^G_i - shortfall, \quad \text{if } Adequate(W^G_i, W^D_i) = False$$

15

and

$$w^p_i = 0 \quad \text{if } Adequate(W^G_i, W^D_i) = True$$

or

$$w^p_i = shortfall \quad \text{if } Adequate(W^G_i, W^D_i) = False,$$

whereby  $Adequate(W^G_i, W^D_i)$  is a function which returns *True* if  $W^D_i$  is

20 adequate to meet  $W^G_i$  in accordance with pre-determined criteria and otherwise returns *False*; and

$$\text{whereby } shortfall = W^G_i - W^D_i.$$

In one embodiment the function  $Adequate(W^G_i, W^D_i)$  is defined as follows:

$$Adequate(W^G_i, W^D_i) = True \quad \text{if } W^G_i < W^D_i$$

25

or

$$Adequate(W^G_i, W^D_i) = False \quad \text{if } W^G_i > W^D_i.$$

In another embodiment the function  $Adequate(W_i^G, W_i^D)$  is further adapted to take into account additional factors such as appropriateness of exposure and/or excessive exposure criteria.

- In accordance with a fifth aspect of the present invention there is provided a
- 5 method of investing within a selected industry, said method including the steps of:
- determining a required weighting within said selected industry;
  - investing internationally within said selected industry only if a domestic market weight in said industry is less than said required weighting within said industry, otherwise;
  - 10 investing exclusively domestically within said selected industry.

In accordance with a sixth aspect of the present invention there is provided an apparatus for determining weightings of an investment portfolio selected from a range of domestic and international financial investments, said apparatus including:

- a memory for storing said range in a plurality of industry based groups;
- 15 an input for definition of a required\_industry\_weighting for each of said industry based groups;
- an input for definition of an available\_domestic\_weighting for each of said industry based groups;
- a data processor for determining a mixture of financial investments within
- 20 each of said industry based groups, whereby said mixture consists of:
  - exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting; otherwise
  - domestic financial investments having a weighting substantially equal
  - 25 to said available\_domestic\_weighting and international financial investments having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting; and

an output for communication of said mixture of financial investments within each of said industry based groups.

In accordance with a seventh aspect of the present invention there is provided an apparatus for determining a mixture of financial investments within a pre-selected industry based group, said apparatus including:

an input for definition of a required\_industry\_weighting for said pre-selected industry based group;

an input for definition of an available\_domestic\_weighting for said pre-selected industry based group;

a data processor for determining the mixture of financial investments within said pre-selected industry based group, whereby said mixture consists of:

exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting; otherwise,

domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international equity investments having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting; and  
an output for communication of said mixture of financial investments.

In accordance with an eighth aspect of the present invention there is provided an apparatus for determining weightings of an investment portfolio selected from a range of domestic and international financial investments, said apparatus including:

a memory for storing said range of domestic and international financial investments in a plurality of groups;

an input for defining a required\_industry\_weighting for each of said groups;

an input for defining an available\_domestic\_weighting for each of said groups;

a data processor for determining the mixture of financial investments within each of said groups, whereby said mixture consists of:

exclusively said domestic financial investments if said  
available\_domestic\_weighting equals or exceeds said required\_industry\_weighting;  
otherwise,

domestic financial investments having a weighting substantially equal to said  
5 available\_domestic\_weighting and international financial investments having a  
weighting substantially equal to said required\_industry\_weighting minus said  
available\_domestic\_weighting; and

an output for communication of said mixture of financial investments within  
each of said groups.

10 In accordance with a ninth aspect of the present invention there is provided  
an apparatus for determining a spread of investments across  $i$  groups of financial  
investments, each of said groups including domestic financial investments and  
international financial investments, said apparatus including:

a) an input for defining a desired weight ( $W_i^G$ ) for each of the  $i$  groups;  
15 b) an input for defining the weight of domestic financial investments ( $W_i^D$ ) for  
each of the  $i$  groups;

c) a data processor for calculating a domestic weight ( $w_i^D$ ) for each of the  $i$   
groups within the spread of investments and an international weight ( $w_i^I$ ) for each of  
the  $i$  groups within the spread of investments as follows:

20  $w_i^D = W_i^G$  if Adequate( $W_i^G, W_i^D$ ) = True

or

$w_i^D = W_i^G - shortfall$ , if Adequate( $W_i^G, W_i^D$ ) = False

and

$w_i^I = 0$  if Adequate( $W_i^G, W_i^D$ ) = True

25 or

$w_i^I = shortfall$  if Adequate( $W_i^G, W_i^D$ ) = False,

whereby  $Adequate(W_i^G, W_i^D)$  is a function which returns *True* if  $W_i^D$  is adequate to meet  $W_i^G$  in accordance with pre-determined criteria and otherwise returns *False*; and

whereby  $shortfall = W_i^G - W_i^D$ .

5           In accordance with a tenth aspect of the present invention there is provided an apparatus for investing within a selected industry, said apparatus including:

an input for determining a required weighting within said selected industry;

investing means for investing internationally within said selected industry only if a domestic market weight in said industry is less than said required weighting within

10   said industry, otherwise;

investing exclusively domestically within said selected industry.

In accordance with an eleventh aspect of the present invention there is provided an investment portfolio having weightings determined in accordance with the method and/or the apparatus as described above.

15           In accordance with a twelfth aspect of the present invention there is provided a mixture of financial investments selected in accordance with the method and/or the apparatus as described above.

In accordance with a thirteenth aspect of the present invention there is provided a spread of investments across  $i$  groups of financial investments determined  
20 in accordance with the method and/or the apparatus as described above.

In accordance with a fourteenth aspect of the present invention there is provided an investment portfolio having weightings determined in accordance with a benchmark index calculated in accordance with the method and/or the apparatus as described above.

25           In accordance with a fifteenth aspect of the present invention there is provided a mixture of financial investments within a pre-selected industry based group determined in accordance with a benchmark index calculated in accordance with the method and/or the apparatus as described above.

In accordance with a sixteenth aspect of the present invention there is provided a spread of investments across  $i$  groups of financial investments determined in accordance with a benchmark index calculated in accordance with the method and/or the apparatus as described above.

5 In accordance with another aspect of the present invention there is provided a computer-implemented method for managing investments including domestic and international financial investments represented by companies and divided into business sectors based on a type of business associated with each company, comprising:

10 selecting a first value associated with a portion of an investment portfolio designated to a business sector and representing an international share of business associated with the business sector; and

determining an investment plan for at least the portion of the investment portfolio based on a relationship between the first value and a second value

15 representing a domestic share of business associated with the business sector.

In one embodiment the step of determining an investment plan includes either:

(i) exclusively selecting domestic financial investments for the investment plan when the second value is equal or exceeds the first value; and

20 (ii) selecting for the investment plan domestic financial investments having a weighting substantially equal to the second value and international financial investments having a weighting substantially equal to a difference between the first value and the second value.

#### **Brief Description of the Figures:**

25 An embodiment of the invention will now be described by way of example only with reference to the accompanying drawings in which:

Figure 1 is a flow chart showing a first method according to the present invention;

Figure 2 is a flow chart showing a second method according to the present invention;

Figure 3 is a bar graph showing a set of desired weights drawn from column 1 of table 1;

5        Figure 4 is a bar graph showing a set of weights of domestic financial investments drawn from column 2 of table 1; and

Figure 5 is a bar graph showing a set of mixtures according to the second embodiment of the present invention drawn from column 3 of table 1.

**Exemplary Detailed Description of Embodiments:**

10        A method for determining weightings of an investment portfolio selected from a range of domestic and international financial investments is illustrated in figure 1. In this embodiment the investment portfolio consists of domestic and international tradable financial products such as financial instruments, securities, equities, shares, futures, options, warrants, bonds and/or promissory notes.

15        The method commences with the step 1 of dividing of the range of domestic and international financial investments into a plurality of groups, for example industry based groups. It is possible for an investor using this embodiment of the present invention to define the groups using whatever criterion is considered suitable. For the sake of example, the industry based groups of this embodiment are consistent  
20        with the Global Industry Classification Standards (GICS). This classification was introduced by Morgan Stanley Capital International (MSCI) and Standard & Poor (S&P) in 1999. The GICS classifies each financial investment into one of:

- 123 sub-industries, each of which belong to one of
- 59 industries, each of which belong to one of
- 25        • 23 industry groups, each of which belong to one of
- 10 sectors.

The industry based groups utilised in this embodiment are the 23 industry groups of the GICS, as listed in the first column of table 1 below. Some possible but non-limiting examples of suitable pre-specified groupings are the Financial Times series or National Accounts such as those prepared by the Australian Bureau of Statistics.

- 5 Yet other embodiments utilise the 123 sub-industries, the 59 industries or the 10 sectors of the GICS as the basis of the industry based groups.

- As used herein, the words "domestic" and the like refer to any one country or regional group of countries. The terms "international" and the like refer to all countries other than the domestic country or regional group of countries. Hence this
- 10 embodiment may be utilised with specific reference to any given country or region by construing the word "domestic" to refer to that country or region. Similarly, the term "domestic" as used herein may be construed so as to refer to any set of financial investments which are to be given preferential treatment in the portfolio. In this case, the term "international" is to be construed so as to refer to those investments of
- 15 interest not falling within the scope of the term "domestic". Additionally, in determining the mix of domestic and international financial investments, this embodiment of the present invention provides the necessary flexibility to incorporate changes to definitions of "domestic financial investments" and "international financial investments". For example, with increasing dual listings and the possibility of
- 20 mergers of stock exchanges into one or more international exchanges, the definition of "domestic financial investments" and "international financial investments" may change over time to reflect the changing characteristics of markets and companies. Hence the investor using this embodiment of the present invention may define domestic financial investments to be based on place of incorporation of the relevant
- 25 company, or the base of the home country stock exchange.

Step 2 of this method involves selecting one of the industry based groups. Preferably a list of industry based groups is selected sequentially. For example the first industry based group to be selected in this embodiment is "Energy". It is then

necessary at step 3 to define a variable referred to in this document as the required\_industry\_weighting for the selected industry based group (that is for the "Energy" group). This variable represents the preferred weighting which the investor proposes to give the selected industry group within the investment portfolio. This variable is most conveniently represented as a percentage of the overall portfolio, however it will be appreciated by those skilled in the art that other representations of the weighting, such as an absolute figure representing the total funds to be invested in the selected industry based group would also suffice provided consequent minor amendments are made to the formulae used.

10 In this embodiment the required\_industry\_weightings for each of the industry based groups are based on the global weight of each industry based group within the MSCI World Index. Examples of these weightings are listed under the heading "World Weight" in column 1 of table 1 below. In other words, the required\_industry\_weighting for the Energy industry based group in this example is 15 6.9%.

Once again, however, other criteria may be used to determine the various values for the required\_industry\_weightings if the investor so chooses. For example, the required\_industry\_weighting may be determined based upon an estimate of the future consumption of investors from suppliers in the selected industry based group.

20 This more complex alternative is an attempt to directly link investment assets with future liabilities.

Industry Group	World Weight	Shortfall		Final Exposure	
		Australia Weight		Aust	Overseas
Energy	6.9%	2.8%	4.1%	2.8%	4.1%

**Table 1**

At step 4 it is necessary to determine a variable referred to in this document as the available\_domestic\_weighting for the selected industry based group. In this embodiment a domestic index is used to determine the available\_domestic\_weighting, for example the ASX/S&P 200 index. Examples of these figures are shown in column 2 of table 1 under the heading "Australia Weight". Hence the available\_domestic\_weighting for the Energy industry based group is 2.8% in this example.

Of course, other sources of statistical information may be utilised in the place of the ASX/S&P200 if desired, for example other benchmark data such as the ASX/S&P300 index. For applications of this embodiment in which the "domestic" country is defined as a country other than Australia, it is possible to utilise a domestic benchmark from that country upon which to base the available\_domestic\_weightings.

One embodiment includes the further step whereby a figure from the domestic index is varied dependent upon pre-determined criteria prior to determining said available\_domestic\_weighting. For example, in one embodiment the available\_domestic\_weighting is a product of the figure from the domestic index and a scaling factor which is dependent upon the pre-determined criteria. More

particularly, the figure extracted from the domestic index is representative of the

Detailed examples of the calculation and use of the factor  $F$  to incorporate the criteria mentioned above are provided below in relation to the second embodiment whereby adaptations of the  $Adequate(W_i^G, W_i^D)$  function are described.

Step 5 involves a consideration as to whether the

5 available\_domestic\_weighting equals or exceeds the required\_industry\_weighting.

In the current example the available\_domestic\_weighting for Energy is 2.8% and the required\_industry\_weighting for Energy is 6.9%. Hence the available\_domestic\_weighting does not equal or exceed the

required\_industry\_weighting and it is therefore necessary to proceed to step 5B. In

10 this step a mixture of financial investments within the Energy group is calculated.

The mixture consists of domestic financial investments in the Energy group having a weighting substantially equal to said available\_domestic\_weighting, that is 2.8%, and international financial investments having a weighting substantially equal to the required\_industry\_weighting (6.9%) minus the available\_domestic\_weighting (2.8%),

15 that is 4.1%.

The international component of the investment portfolio (eg, the 4.1% weighting for the Energy industry based group) may be invested internationally according to the discretion of the investor. In one embodiment, however, the international investments are spread across foreign countries or regions in the same

20 ratio as an international benchmark, for example the MSCI World Index. This approach is particularly suited to the formulation of a "standard" benchmark for the inventive method as applied to each domestic market. In yet another embodiment the weights of the international investments for each specified industry groups in each foreign country or region are determined so that the addition of all industry

25 groups in a foreign country is sufficiently close to a specified desired exposure to that foreign country (and this applies to each foreign country). One method of selecting the desired weights for each foreign country is based on the ratio of country weights in the MSCI World Index, thus ensuring that the relativities of foreign country weights

is similar to the selected international index. This method is likely to use some optimization techniques to solve the problem of selecting the weights for each industry group in each foreign country in order to obtain the desired international industry weights in each industry group whilst having the weight to each foreign country close to that desired. One such optimization method minimizes the sum of squares of deviations of weight of each foreign country from the desired weight.

After calculating the mixture for the Energy group, it is necessary to return to step 2 and select the Materials group. In step 3 it would be noted that the required\_industry\_weighting for Materials is 3.8%. Step 4 determines that the available\_domestic\_weighting for Materials is 15.8%. The comparison of step 5 determines that the available\_domestic\_weighting (15.8%) exceeds the required\_industry\_weighting (3.8%). Hence the calculation of the mixture for the Materials Group takes place at step 5A. In this step the mixture consists exclusively of domestic financial investments having a total weighting in the portfolio of 3.8%, that is, substantially equal to the required\_industry\_weighting.

Steps 2 to 5 (including 5A or 5B as appropriate) are repeated with regard to each of the industry based groups in turn until mixtures of financial investments for all of the industry based groups have been determined. The mixtures in each industry based group define the investment portfolio, as shown in the third column of table 1.

In some applications the investment portfolio determined by the present invention will constitute only a component of an overall portfolio which may include other separate financial investments. In this case the weightings used in the present method should represent the weightings with regard to the component to be determined by the present invention. For example a desired weighting of 4% for a particular group indicates that financial investments in that group are to constitute 4% of the component of the overall portfolio which is to be determined by the present invention.

In yet other embodiments of the invention (not illustrated) the inventive method is applied to a single group rather than to all of the groups within the pre-selected range of financial investments. This embodiment essentially involves executing steps 2 to 5 (including 5a or 5b as appropriate) once in relation to the  
5 single group of interest.

In the embodiment illustrated in figure 1 the inventive method is applied sequentially to each industry based group in turn, although it is not necessary that the steps be performed in this order. For example, in the second embodiment illustrated in figure 2, available\_domestic\_weightings for all of the groups are  
10 determined firstly in step 10, then the required\_industry\_weightings are determined for all of the groups in step 11, and finally the mixtures for each of the industry based groups are calculated at steps 12 to 16. More particularly, the second embodiment of the invention concerns a method of determining a spread of investments across  $i$  groups of financial investments, each of the groups including domestic financial  
15 investments and international financial investments. Once again for the purposes of example, this embodiment shall employ the 23 industry groups of the GICS, in other words  $i = 23$ . A second method commences at Step 10 at which a desired weight ( $W_i^G$ ) for each of the  $i$  groups is defined. Hence this step defines the following set:  
 $\{W_1^G, W_2^G, \dots, W_{23}^G\}$ . This set is shown in chart form in figure 3. In each of  
20 the charts shown in figures 3, 4 and 5 the industry based groups are arranged along the X-axis in accordance with the reference number  $i$ . In other words, the number 1 represents the "Energy" group, the number 2 represents the "Materials" group, and so on.

Each of the desired weightings  $W_i^G$  may be calculated based upon any criteria  
25 which the investor chooses to employ. For this example the weightings  $W_i^G$  are based upon the global weight of each industry based group within a global index such as the MSCI World Index, as for the first embodiment.

At step 11 the weight of domestic financial investments ( $W^D_i$ ) for each of the  $i$  groups is determined. Hence this step defines the following set:

$\{W^D_1, W^D_2, \dots, W^D_{23}\}$ . This set is shown in figure 4.

Each of the weightings  $W^D_i$  may be calculated based upon any criteria which the investor chooses to employ. For this example the weightings  $W^D_i$  are based upon a domestic index such as the ASX/S&P 200 index, as for the first embodiment.

At step 12 the  $Adequate(W^G_i, W^D_i)$  function is calculated for the  $i$ -th group. This is a function which returns *True* if  $W^D_i$  is adequate to meet  $W^G_i$  in accordance with pre-determined criteria. Otherwise the  $Adequate(W^G_i, W^D_i)$  function returns *False*. In this embodiment the values of *True* and *False* are 1 and 0 respectively, although other values may be utilised. In one embodiment the function  $Adequate(W^G_i, W^D_i)$  is defined as follows:

$$Adequate(W^G_i, W^D_i) = True \quad \text{if } W^G_i < W^D_i$$

or

$$Adequate(W^G_i, W^D_i) = False \quad \text{if } W^G_i > W^D_i$$

If the  $Adequate(W^G_i, W^D_i)$  function returns *True*, step 13 directs the method to step 14 at which the domestic weight ( $w^d_i$ ) and the international weight ( $w^p_i$ ) for the  $i$ -th group is calculated as follows:

$$w^d_i = W^G_i$$

and

$$w^p_i = 0.$$

If the  $Adequate(W^G_i, W^D_i)$  function returns *False*, step 13 directs the method to step 15 at which the domestic weight ( $w^d_i$ ) and the international weight ( $w^p_i$ ) for the  $i$ -th group is calculated as follows:

$$w^d_i = W^G_i - shortfall$$

and

$$w^p_i = shortfall.$$

An alternative method of determining the appropriate domestic weighting is by adapting the  $Adequate(W^G_i, W^D_i)$  function to take into account other criteria, for example the appropriateness of exposure and/or excessive exposure. Some examples of such adaptation involve a modification of the equation for  $w^D_i$  when the function  $Adequate()$  is False by incorporating a scaling factor,  $F$ , as follows:

$$w^D_i = \text{Minimum}(W^G_i, W^D_i * F) \quad \text{if } Adequate(W^G_i, W^D_i) = \text{False}$$

where  $1 \geq F \geq 0$ , and  $F$  is a function relating to the adoption of the determination of adequacy. Such modifications can be implemented using the alternate definition of  $Adequate()$ , or in conjunction with the definition in the above embodiment.

Additionally,  $Adequacy()$  and the determination of  $w^D_i$  may combine a number of aspects of adequacy in which case a method for combining the various aspects of  $Adequacy()$  would apply. An example of a method for combining the various aspects of  $Adequacy()$  would be to apply each aspect one at a time, ie obtain the greatest weight for the domestic industry groups which satisfy all the adequacy criteria. It is noted that some of the factors addressed by these adaptations may alternatively be factored into the determination of the available domestic weighting in the manner set out above whereby the domestic weighting is multiplied by the factor  $F$ .

The function  $Adequate(W^G_i, W^D_i)$  may be adapted to take into account difficulty in trading equity investments associated with very small companies. For example, one may consider that the liquidity of a company, as measured by the average daily trading volume over the previous year, is inadequate if it is less than a specified value for each stock. The specified value for each stock could, for example, relate to the trading volume expected from typical cash flows into or out of the investment portfolio. In this example, if we determined that 30% of the companies in the industry group being considered have inadequate liquidity, then we could specify

$$F = (1 - \text{percent of illiquid companies}), \quad \text{eg } 70\%$$

$$Adequate(W^G_i, W^D_i) = \text{False} \quad \text{if } W^D_i * F < W^G_i$$

and obtain the domestic industry group from those companies which meet the liquidity requirements.

The function  $Adequate(W^G_i, W^D_i)$  may be adapted to take into account appropriateness of companies associated with domestic equities. For example, if the domestic companies in an industry group have business activities which are in a very narrow field, then they could be considered inadequate. An example would be if the domestic pharmaceutical companies produced medicines in a very specialist and narrow field of use within the community, eg anti rejection drugs. In this adaptation of *Adequate*,

10 
$$Adequate(W^G_i, W^D_i) = \text{False}$$

if industry coverage of  $W^D_i$  is sufficiently less than industry coverage of  $W^G_i$  and  $F$  is a function of the degree of the coverage of the industry group from the available domestic companies, eg if the domestic companies only cover 40% of the breadth of activities of the industry group, then  $F$  is set equal to 40%. Alternatively one may need to further subdivide this industry group into industries and sub-industries and apply adequacy rules to those groups.

The function  $Adequate(W^G_i, W^D_i)$  may be adapted to take into account the place of incorporation of a company associated with a domestic equity, for example the function may be adapted to favour equity investments associated with companies having a place of incorporation within a pre-selected region or to favour equity investments associated with companies having a home country stock exchange within a pre-selected region. If we determine that  $F\%$  of companies in an industry group have the appropriate place of incorporation, then we could specify

20 
$$Adequate(W^G_i, W^D_i) = \text{False} \quad \text{if } W^D_i * F < W^G_i$$

25 and obtain the domestic industry group from those companies which meet the place of incorporation requirements.

The function  $Adequate(W^G_i, W^D_i)$  may be adapted to take into account risk diversification. For example, if inclusion of international industry groups significantly

lowers the risk of the investment portfolio, then the domestic exposure could be reduced. This will possibly occur for those industry groups that are less subject to globalisation factors. Risk has many definitions, and an example is volatility of returns. An adoption to the formulation of *Adequate()* would be

$$5 \quad Adequate(W^G_i, W^D_i) = \text{False}$$

if  $Risk(W^G_i)$  is sufficiently less than  $Risk(W^D_i)$

and  $F$  is proportional to the degree of the risk reduction arising from the additional international exposure. The functional form of  $F$  depends on one's risk tolerance, and those skilled in the art of investing will have their own "functional" forms.

- 10        The function *Adequate*( $W^G_i, W^D_i$ ) may be adapted to take into account the market capitalisation of financial investments, for example the investor may choose to favour, say, large companies in comparison to small and medium sized companies. For example, if we determine that  $F\%$  of companies in an industry group are in the required market capitalisation range (eg in the Top 50% of the market) then
- 15 we could specify

$$Adequate(W^G_i, W^D_i) = \text{False} \quad \text{if } W^D_i * F < W^G_i$$

and obtain the domestic industry group exposure from those companies which meet the market capitalisation requirements.

- 20        The function *Adequate*( $W^G_i, W^D_i$ ) may be adapted to take into account an assessment of the value of an investment or a pre-selected group, for example an investor may choose to favour a particular company or industry based group. For example, if inclusion of a domestic industry group lowers the assessment of value of an investment portfolio, then the domestic exposure could be reduced. Investment managers assess value in a multitude of ways, but they generally relate to the
- 25 expectations of the future return from an investment. If we denote *Return()* to reflect an assessment of expected return of an investment, then an adaptation to the formulation of *Adequate()* would be

$$Adequate(W^G_i, W^D_i) = \text{False}$$

if  $Return(W^G_i)$  is sufficiently less than  $Return(W^D_i)$

and  $F$  is a function where  $F$  is smaller for a greater degree of the increase in  $Return()$  arising from inclusion of the additional international exposure. The form of the function  $Return()$  depends on one's risk tolerance, and those skilled in the art of

- 5 investing will have their own "functional" forms. One common form is to risk adjust the returns as follows

$$Return() = Expected\ Return() - (Risk\ Tolerance) * Variance\ of\ Expected\ Return().$$

The function  $Adequate(W^G_i, W^D_i)$  may be adapted to take into account an assessment of any one or more of the following aspects of an investment:

- 10        Stock liquidity  
          Financial risk  
          Management risk  
          Physical security  
          Political risk  
15        Operational leverage (leverage to economic cycle)  
          Expected risk premium or  
          Exposure to inflation

Examples of application of these aspects would follow the examples given for the adoption of adequacy for market capitalisation, risk or return considerations.

- 20        The function  $Adequate(W^G_i, W^D_i)$  may be adapted to take into account an assessment of the growth potential of an investment. Examples of application of the aspect would follow the example for return considerations.

- Finally, the function  $Adequate(W^G_i, W^D_i)$  and/or the value of *shortfall* may be adapted to take into account maximum or minimum limits on either international or  
25 domestic expenditure, for example an investor may choose to limit the weighting of international investments to a maximum of, say, 4% in any one group. Another example of the latter type of adaptation may be implemented if an investor wishes to limit international exposure to no more than, say, 40%, in line with the current

average exposure of Australian superannuation funds to international investments. In the above example, the total international exposure calculated is 43.0%. Accordingly the limit of 40% can be included in the specification of *Adequacy()* and *shortfall*. One methodology is to initially calculate the domestic and international weights as in the

5 above table, then if the overall international weight is over 40%, scale up all the domestic weights on a pro rata basis to achieve the desired reduction in the international exposure to 40%.

Another method of limiting international exposure to a particular desired value is to only adjust the domestic weights of industry groups where there is a shortfall.

10 For example, it may be desired to have a total domestic weight of 60% and the domestic weight in all the industry groups is 57%. If the total domestic weight of industry groups where there is a shortfall is 23.2%, it is possible to multiply the domestic weights of the industry groups where there is a shortfall by the following factor:

15 
$$(\text{desired domestic weight} - (\text{total domestic weight} - \text{total weight of domestic industry groups where there is a shortfall})) / (\text{total weight of domestic industry groups where there is a shortfall})$$

ie:

$$(60\% - (57\% - 23.2\%)) / 23.2\% = 1.13$$

20 and it is possible to decrease the international weight of those industry groups by the same absolute percentage as we increased the domestic weight to achieve a total domestic weight of 60% and thus an international weight of 40%.

In applying these adjustments, it is preferable to be mindful of industry groups where the resultant pro rata increases in the domestic weight may result in the

25 domestic weight being greater than the global weight. If that occurs, then it is possible to set the domestic weight of that industry group to the global weight and undertake further iterations using the above pro rata adjustment. This method will

thus result in a set of domestic and international weights which are subject to the structure of the industry group weights.

Similarly, if the total domestic weight is greater than a specified desired value, then similar pro rata adjustments can be used to ensure that the domestic weight is  
5 decreased.

The value of *shortfall* for each group  $i$  is defined as  $W_i^G - W_i^D$ . In other words, *shortfall* is the extent to which the weight of the domestic financial investments for each group ( $W_i^D$ ) falls short of the desired weight for each group ( $W_i^G$ ).

The method then cycles back to step 12 and the  $Adequate(W_i^G, W_i^D)$  function  
10 is calculated for the next group. This cycle is reiterated until all of the  $i$ -th groups have been considered. Hence the method defines the following two sets:

domestic weights:  $\{w_1^D, w_2^D, \dots, w_{23}^D\}$ , shown as the solid components of the bars in figure 5; and

international weights:  $\{w_1^I, w_2^I, \dots, w_{23}^I\}$  shown as the diagonally striped  
15 components of the bars in figure 5.

Together, these sets define the weights of the spread of investments as given by the overall bar graph of figure 5. It can be seen from figure 5 and table 1 that in Australia banks represent 12.0% whereas they represent only 7.0% globally. Thus the domestic market provides more than adequate exposure to the "Bank" industry  
20 group and this embodiment of the present invention therefore allocates the required 7.0% to the domestic banking industry and nothing internationally. In contrast, the typical prior art technique using a fixed Australian to International ratio of 60: 40 would result in a banking exposure of 10.0% (that is,  $60\% * 12\% + 40\% * 7.0\%$ ). Hence this particular embodiment of the present invention addresses the bias to  
25 large domestic industries that is inherent in the prior art technique since dominating domestic industries are scaled down to the global weights. Further, a bias within a domestic market toward one particular company is addressed by this embodiment in a similar manner.

In the pharmaceuticals and biotechnology group the Australian market weight is very low at 0.5% compared to the global weight of 8.0%. Thus this particular embodiment of the present invention allocates 0.5% to domestic investments and the 7.5% shortfall to international investments. In comparison, the prior art 60:40

5 technique would allocate a total exposure to the Pharmaceutical and Technology group of 3.5% (that is,  $60\% \times 0.5\% + 40\% \times 8.0\%$ ). Hence this particular embodiment of the present invention addresses situations wherein the domestic market is under-represented in a given industry based group since under-represented domestic industries are scaled up to the global weights.

10 This embodiment aligns exposure to industry groups available for investment worldwide. Thus the preferred embodiment delivers the diversification benefits from a reasonable spread of industry groups.

Additionally, this embodiment still obtains country diversification benefits from the spread of countries within and/or across the industry groups. The preferred  
15 embodiment explicitly obtains diversification across industry groups and implicitly obtains country diversification.

This embodiment only results in an international investment if the local market has a shortfall in an industry group. Thus this embodiment does not double up in industry groups where adequate exposure is available domestically (e.g. resources,  
20 banks). This aspect may have social and economic benefits for the domestic country.

Conversely, it is reasonable that if the domestic market does not provide adequate exposure to an industry group, then an investor should look internationally to fill that shortfall (e.g. Pharmaceuticals, Autos in the case of Australia or Energy in  
25 Japan).

It will be appreciated by those skilled in the art that both the first and second embodiments of the invention implement substantially the same method, albeit

expressed in slightly different terms. In essence, each of these embodiments include the steps of:

determining a required weighting within a selected industry;

investing internationally within the selected industry only if a domestic market

5 weight in the industry is less than the required weighting within that industry, otherwise;

investing exclusively domestically within the selected industry.

In a further embodiment computer software is adapted to perform the inventive method. Data representative of the software is stored on a computer

10 readable medium such as a magnetic disk, magnetic tape, compact disk, hard disk, or other data storage devices known in the art. In another embodiment the software is centrally stored at an accessible site, for example on the internet, an intranet or extranet in accordance with the known Application Server Provider (ASP) model of software delivery.

15 Another possible embodiment of an apparatus for selecting an investment portfolio from a range of domestic and international financial investments is preferably implemented in a computing environment with software adapted to configure one or more computers to function as the apparatus. The apparatus includes a memory for storing the range in a plurality of industry based groups.

20 Typically this memory is of the Random Access Memory (RAM) kind, however other known types of memory or data storage devices such as Read Only Memory (ROM), Electronically Programmable Read Only Memory (EPROM), magnetic data storage devices such as floppy disks, hard disks, zip drives etc and optical data storage devices such as compact disk readers (CD ROMS) and Digital Video Disk (DVD)  
25 drives etc may also fulfil this function. In some embodiments the memory is disposed remotely, for example in a remotely accessible database.

The preferred device has an input for definition of the required\_industry\_weighting variables for each of the industry based groups.

Similarly, the available\_domestic\_weighting variable for each of the industry based groups is defined via the input. These variables are preferably also stored in the memory, preferably in the form of a database or the like. In one embodiment the input is manually operated. For example an operator may input the required

5 variables into the apparatus via a keyboard, mouse or other known input device. In other embodiments the input is automatic. In one embodiment the variables are downloaded from a remote data store via a communicator, for example a modem or cable data connection. The communicator communicates with one or more financial databases, or other financial information sources, for example one or more  
10 stockmarkets. The communicator is adapted to receive data indicative of domestic weightings and global weightings for each of the industry based groups. This data is used by the processor to define the available\_domestic\_weightings and the required\_industry\_weightings respectively. In yet other embodiments these variables are automatically read from any one of the data storage devices mentioned above.

15 The preferred device includes a data processor which is used for determining a mixture of financial investments within each of said industry based groups in accordance with the method described above. The data processor is preferably one or more central processing units (CPU's) either including or having access to a calculator, for example a maths co-processor.

20 The preferred device also includes an output for communication of the mixture of financial investments within each of the industry based groups. Various outputs may be utilised, such as:

visual outputs for example monitors, liquid crystal displays (LCD's), plasma screens, printers, plotters, etc;

25 audible outputs for example speakers, etc

electronic signals for example digital signals, audio signals, visual signals, etc; and/or

a communicator, for example a modem or other data exchanging connection, adapted to automatically place buying orders in accordance with said mixtures. The buying orders are preferably received by one or more financial institutions, such as stockmarkets.

5 Yet another embodiment of the invention is an apparatus for investing within a selected industry. The apparatus includes an input for determining a required weighting within said selected industry. Any one or more of the inputs mentioned above are also applicable to this embodiment. The apparatus further includes investing means for investing internationally within said selected industry only if a  
10 domestic market weight in said industry is less than said required weighting within said industry. Otherwise the investing means invests exclusively domestically within said selected industry. The investing means of one embodiment is a communicator connected to a financial institution as described above. In another embodiment the investing means provides an output which is indicative of the amounts to be invested.  
15 This output then forms the basis of the investor's investments. Any one or more of the outputs mentioned above are also applicable to this embodiment.

Rather than determining a portfolio with the aim of investing in that portfolio, the invention may also be employed to determine a portfolio for use as an index, benchmark or hypothetical portfolio which may be used for, *inter alia*, performance  
20 measurement and performance comparisons, guidance for country and/or industry exposures, performance and/or risk analysis, and other calculations and comparisons. Hence, as used in this document, the term "investment portfolio" is to be construed as including "benchmark", "index" and "hypothetical portfolio" within its scope.

25 Although the invention has been described with reference to specific examples, it will be appreciated that the invention may be embodied in many other forms.

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:-

- 5 1. A method for determining weightings of an investment portfolio selected from a range of domestic and international financial investments, said method including the steps of:
- a) dividing said range of domestic and international financial investments into a plurality of industry based groups;
  - 10 b) selecting one of said industry based groups;
  - c) determining a required\_industry\_weighting for said selected industry based group;
  - d) determining an available\_domestic\_weighting for said selected industry based group;
  - 15 e) determining a mixture of financial investments within said selected industry based group, whereby said mixture consists of:
    - e1) exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting; otherwise
    - 20 e2) domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international financial investments having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting; and
    - f) repeating steps b) to e) until mixtures of financial investments for all of said
  - 25 industry based groups have been determined, thereby forming the weighting of said investment portfolio.
2. A method according to claim 1 wherein the domestic financial investments in step e1 have a weighting substantially equal to said required\_industry\_weighting.

3. A method according to claim 1 wherein the industry based groups of step a) are consistent with the Global Industry Classification Standards (GICS).
4. A method according to claim 1 wherein the industry based groups are consistent with the 23 industry groups as defined in the Global Industry Classification
- 5 Standards.
5. A method according to claim 1 wherein the required\_industry\_weighting determined in step c with reference to a selected industry based group is substantially equal to a global weight of said industry based group within the MSCI World Index.
- 10 6. A method according to claim 1 wherein the required\_industry\_weighting determined in step c with reference to a selected industry based group is based upon an estimate of the future consumption from suppliers in said industry based group.
7. A method according to claim 1 wherein a domestic index is used to determine the available\_domestic\_weighting in step d.
- 15 8. A method according to claim 7 wherein a figure from said domestic index is varied dependent upon pre-determined criteria prior to determining said available\_domestic\_weighting.
9. A method according to claim 8 wherein said available\_domestic\_weighting is a product of said figure and a scaling factor which is dependent upon said pre-
- 20 determined criteria.
10. A method according to claim 8 wherein said criteria includes appropriateness of exposure and/or excessive exposure criteria.
11. A method according to claim 8 wherein said criteria includes difficulty in trading equity investments associated with very small companies.
- 25 12. A method according to claim 8 wherein said criteria includes appropriateness of companies associated with domestic equities.
13. A method according to claim 8 wherein said criteria includes the place of incorporation of a company associated with a domestic equity.

14. A method according to claim 13 wherein said criteria includes equity investments associated with companies having a place of incorporation within a pre-selected region.
15. A method according to claim 8 wherein said criteria includes equity investments  
5 associated with companies having a home country stock exchange within a pre-selected region.
16. A method according to claim 8 wherein said criteria includes maximum or minimum limits on either international or domestic expenditure.
17. A method according to claim 8 wherein said criteria includes risk diversification.
- 10 18. A method according to claim 8 wherein said criteria includes the market capitalisation of financial investments.
19. A method according to claim 8 wherein said criteria includes an assessment of the value of an investment or a pre-selected group.
20. A method according to claim 8 wherein said criteria includes an assessment of  
15 the growth potential of an investment.
21. A method according to claim 8 wherein said criteria includes an assessment of any one or more of the following aspects of an investment:
- Stock liquidity;
  - Financial risk;
  - 20 Management risk;
  - Physical security;
  - Political risk;
  - Operational leverage (leverage to economic cycle);
  - Expected risk premium; and/or
  - 25 Exposure to inflation.
22. A method according to claim 1 wherein said financial investments include any one or more of the following:

financial instruments; securities; equities; shares; futures; options; warrants; bonds; promissory notes; or other tradable financial products.

23 A method of determining a mixture of financial investments within a pre-selected industry based group, said method including:

- 5           a) determining a required\_industry\_weighting for said pre-selected industry based group;
- b) determining an available\_domestic\_weighting for said pre-selected industry based group;
- c) determining the mixture of financial investments within said pre-selected

10 industry based group, whereby said mixture consists of:

            c1) exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting; otherwise,

- 15           c2) domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international equity investments having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting.

24. A method according to claim 23 wherein the domestic financial investments in step c1 have a weighting substantially equal to said required\_industry\_weighting.

20 25. A method for determining weightings of a portfolio selected from a range of domestic and international financial investments, said method including the steps of:

- a) dividing said range of domestic and international financial investments into a plurality of groups;
- b) selecting one of said groups;
- 25           c) determining a required\_industry\_weighting for said selected group based upon investor criteria;
- d) determining an available\_domestic\_weighting for said selected group based upon statistical information;

e) determining a mixture of financial investments within said selected group, whereby said mixture consists of:

e1) exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting;

5 otherwise,

e2) domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international financial investments having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting; and

10 f) repeating steps b) to e) until mixtures of financial investments or all of said groups have been determined, thereby forming the weighting of said investment portfolio.

26. A method according to claim 25 wherein said statistical information is a domestic benchmark or index.

15 27. A method according to claim 26 wherein said investor criteria is based upon an international benchmark or index.

28. A method of determining a spread of investments across  $i$  groups of financial investments, each of said groups including domestic financial investments and international financial investments, said method including the following steps for each  
20 of the  $i$  groups:

a) defining a desired weight ( $W_i^G$ );

b) determining the weight of domestic financial investments ( $W_i^D$ );

c) calculating a domestic weight ( $w_i^D$ ) within the spread of investments and a international weight ( $w_i^I$ ) within the spread of investments as follows:

25  $w_i^D = W_i^G$  if  $Adequate(W_i^G, W_i^D) = True$

or

$w_i^D = W_i^G - shortfall$ , if  $Adequate(W_i^G, W_i^D) = False$

and

$w_i^p = 0$  if  $Adequate(W_i^G, W_i^p) = True$

or

$w_i^p = shortfall$  if  $Adequate(W_i^G, W_i^p) = False$ ,

whereby  $Adequate(W_i^G, W_i^p)$  is a function which returns *True* if  $W_i^p$  is

5 adequate to meet  $W_i^G$  in accordance with pre-determined criteria and otherwise returns *False*; and

whereby  $shortfall = W_i^G - W_i^p$ .

29. A method according to 28 wherein the function  $Adequate(W_i^G, W_i^p)$  is defined as follows:

10  $Adequate(W_i^G, W_i^p) = True$  if  $W_i^G < W_i^p$

or

$Adequate(W_i^G, W_i^p) = False$  if  $W_i^G > W_i^p$

30. A method according to claim 28 wherein the function  $Adequate(W_i^G, W_i^p)$  is adapted to take into account appropriateness of exposure and/or excessive exposure  
15 criteria.

31. A method according to claim 28 wherein the function  $Adequate(W_i^G, W_i^p)$  is adapted to take into account difficulty in trading equity investments associated with very small companies.

32. A method according to claim 28 wherein the function  $Adequate(W_i^G, W_i^p)$  is  
20 adapted to take into account appropriateness of companies associated with domestic equities.

33. A method according to claim 28 wherein the function  $Adequate(W_i^G, W_i^p)$  is adapted to take into account the place of incorporation of a company associated with a domestic equity.

25 34. A method according to claim 33 wherein  $Adequate(W_i^G, W_i^p)$  is adapted to favour equity investments associated with companies having a place of incorporation within a pre-selected region.

35. A method according to claim 34 wherein  $Adequate(W^G_i, W^D_i)$  is adapted to favour equity investments associated with companies having a home country stock exchange within a pre-selected region.

36. A method according to claim 28 wherein the function  $Adequate(W^G_i, W^D_i)$  and/or  
5 the value of *shortfall* is adapted to take into account maximum or minimum limits on either international or domestic expenditure.

37. A method according to claim 28 wherein the function  $Adequate(W^G_i, W^D_i)$  is adapted to take into account risk diversification.

38. A method according to claim 28 wherein the function  $Adequate(W^G_i, W^D_i)$  is  
10 adapted to take into account the market capitalisation of financial investments.

39. A method according to claim 28 wherein the function  $Adequate(W^G_i, W^D_i)$  is adapted to take into account an assessment of the value of an investment or a pre-selected group.

40. A method according to claim 28 wherein the function  $Adequate(W^G_i, W^D_i)$  is  
15 adapted to take into account an assessment of the growth potential of an investment.

41. A method according to claim 28 wherein the function  $Adequate(W^G_i, W^D_i)$  is adapted to take into account an assessment of any one or more of the following aspects of an investment:

- Stock liquidity;
- 20 Financial risk;
- Management risk;
- Physical security;
- Political risk;
- Operational leverage (leverage to economic cycle);
- 25 Expected risk premium; and/or
- Exposure to inflation.

42. A method of investing within a selected industry, said method including the steps of:

determining a required weighting within said selected industry;

investing internationally within said selected industry only if a domestic market weight in said industry is less than said required weighting within said industry, otherwise;

5 investing exclusively domestically within said selected industry.

43. Computer software adapted to perform the method as defined in any one of claims 1, 9, 11, 14 or 28.

44. A computer readable medium including data representative of software according to claim 43.

10 45. An apparatus for determining weightings of an investment portfolio selected from a range of domestic and international financial investments, said apparatus including:

a memory for storing said range in a plurality of industry based groups;

an input for definition of a required\_industry\_weighting for each of said industry based groups;

15 an input for definition of an available\_domestic\_weighting for each of said industry based groups;

a data processor for determining a mixture of financial investments within each of said industry based groups, whereby said mixture consists of:

exclusively said domestic financial investments if said

20 available\_domestic\_weighting equals or exceeds said

required\_industry\_weighting; otherwise

domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international financial investments having a weighting substantially equal to said required\_industry\_weighting minus said

25 available\_domestic\_weighting; and

an output for communication of said mixture of financial investments within each of said industry based groups.

46. An apparatus according to claim 45, said apparatus being implemented in a computing environment.

47. An apparatus according to claim 46 wherein said computing environment includes software adapted to configure a computer to function as said apparatus.

5 48. A computer readable medium including data representative of software according to claim 47.

49. An apparatus according to claim 45 wherein said input includes a communicator adapted to receive statistical financial data.

50. An apparatus according to claim 49 wherein said communicator is adapted to  
10 receive data indicative of global weightings for each of said industry based groups and to define said required\_industry\_weightings in accordance therewith.

51. An apparatus according to claim 50 wherein said communicator is adapted to receive data indicative of domestic weighting for each of said industry based groups and to define said available\_domestic\_weightings in accordance therewith.

15 52. An apparatus according to claim 45 wherein the output includes a communicator adapted to automatically place buying orders in accordance with said mixtures.

53. An apparatus for determining a mixture of financial investments within a pre-selected industry based group, said apparatus including:

an input for definition of a required\_industry\_weighting for said pre-selected  
20 industry based group;

an input for definition of an available\_domestic\_weighting for said pre-selected industry based group;

a data processor for determining the mixture of financial investments within said pre-selected industry based group, whereby said mixture consists of:

25 exclusively said domestic financial investments if said available\_domestic\_weighting equals or exceeds said required\_industry\_weighting; otherwise,

domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international equity investments having a weighting substantially equal to said required\_industry\_weighting minus said available\_domestic\_weighting; and

5 an output for communication of said mixture of financial investments.

54. An apparatus for determining weightings of an investment portfolio selected from a range of domestic and international financial investments, said apparatus including:

a memory for storing said range of domestic and international financial investments in a plurality of groups;

10 an input for defining a required\_industry\_weighting for each of said groups;  
an input for defining an available\_domestic\_weighting for each of said groups;  
a data processor for determining the mixture of financial investments within each of said groups, whereby said mixture consists of:

exclusively said domestic financial investments if said

15 available\_domestic\_weighting equals or exceeds said required\_industry\_weighting;  
otherwise,

domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting and international financial investments having a weighting substantially equal to said required\_industry\_weighting minus said

20 available\_domestic\_weighting; and

an output for communication of said mixture of financial investments within each of said groups.

55. A apparatus for determining a spread of investments across  $i$  groups of financial investments, each of said groups including domestic financial investments and

25 international financial investments, said apparatus including:

a) an input for defining a desired weight ( $W_i^G$ ) for each of the  $i$  groups;

b) an input for defining the weight of domestic financial investments ( $W_i^D$ ) for each of the  $i$  groups;

c) a data processor for calculating a domestic weight ( $w_i^d$ ) for each of the  $i$  groups within the spread of investments and a international weight ( $w_i^p$ ) for each of the  $i$  groups within the spread of investments as follows:

$$\begin{aligned} &w_i^d = W_i^G, && \text{if } Adequate(W_i^G, W_i^D) = True \\ 5 & && \text{or} \\ &w_i^d = W_i^G - shortfall, && \text{if } Adequate(W_i^G, W_i^D) = False \\ & && \text{and} \\ &w_i^p = 0 && \text{if } Adequate(W_i^G, W_i^D) = True \\ & && \text{or} \\ 10 &w_i^p = shortfall && \text{if } Adequate(W_i^G, W_i^D) = False, \end{aligned}$$

whereby  $Adequate(W_i^G, W_i^D)$  is a function which returns *True* if  $W_i^D$  is adequate to meet  $W_i^G$  in accordance with pre-determined criteria and otherwise returns *False*; and

whereby  $shortfall = W_i^G - W_i^D$ .

- 15 56. An apparatus for investing within a selected industry, said apparatus including:
- an input for determining a required weighting within said selected industry;
  - investing means for investing internationally within said selected industry only if a domestic market weight in said industry is less than said required weighting within said industry, otherwise;
- 20 investing exclusively domestically within said selected industry.
57. An apparatus according to claim 56 wherein said investing means is a communicator.
58. An apparatus according to claim 57 wherein said communicator is adapted to send electronic buying signals via a communications network to a stockmarket or
- 25 similar financial institution.
59. An investment portfolio having weightings determined in accordance with the method of claim 1 or 25 or the apparatus of claim 45 or 54.

60. A mixture of financial investments within a pre-selected industry based group determined in accordance with the method of claim 23 or the apparatus of claim 53.

61. A spread of investments across  $i$  groups of financial investments determined in accordance with the method of claim 28 or the apparatus of claim 55.

5 62. An investment portfolio having weightings determined in accordance with a benchmark index calculated in accordance with the method of claim 1 or the apparatus of claim 45.

63. A mixture of financial investments within a pre-selected industry based group determined in accordance a benchmark index calculated in accordance with the  
10 method of claim 23 or the apparatus of claim 53.

64. A spread of investments across  $i$  groups of financial investments determined in accordance with a benchmark index calculated in accordance with the method of claim 28 or the apparatus of claim 55.

65. A computer-implemented method for managing investments including domestic  
15 and international financial investments represented by companies and divided into business sectors based on a type of business associated with each company, comprising:

selecting a first value associated with a portion of an investment portfolio designated to a business sector and representing an international share of business  
20 associated with the business sector; and

determining an investment plan for at least the portion of the investment portfolio based on a relationship between the first value and a second value representing a domestic share of business associated with the business sector.

66. The method of claim 65 wherein determining an investment plan, includes either:

25 (i) exclusively selecting domestic financial investments for the investment plan when the second value is equal or exceeds the first value; and

(ii) selecting for the investment plan domestic financial investments having a weighting substantially equal to the second value and international financial

investments having a weighting substantially equal to a difference between the first value and the second value.

## ABSTRACT

A method for determining weightings of an investment portfolio selected from a range of domestic and international financial investments is illustrated in figure 1. The method commences (step 1) with dividing of the range of domestic and international financial investments into a plurality of groups, for example industry based groups. Step 2 of this method involves selecting one of the industry based groups. It is then necessary (step 3) to define a variable referred to in this document as the required\_industry\_weighting for the selected industry based group. This variable represents the preferred weighting which the investor proposes to give the selected industry group within the investment portfolio. Next (step 4) it is necessary to determine a variable referred to in this document as the available\_domestic\_weighting for the selected industry based group. In an embodiment a domestic index is used to determine the available\_domestic\_weighting, for example the ASX/S&P 200 index. Step 5 involves a consideration as to whether the available\_domestic\_weighting equals or exceeds the required\_industry\_weighting. If the comparison of step 5 determines that the available\_domestic\_weighting is equal to or exceeds the required\_industry\_weighting then the calculation of the mixture takes place at step 5A whereby the mixture consists exclusively of domestic financial investments. If the comparison of step 5 determines that the available\_domestic\_weighting is less than the required\_industry\_weighting then the calculation of the mixture takes place at step 5B whereby the mixture consists of:

- domestic financial investments having a weighting substantially equal to said available\_domestic\_weighting, and;
- international financial investments having a weighting substantially equal to the required\_industry\_weighting minus the available\_domestic\_weighting.

This procedure is repeated until mixtures have been calculated for all of the groups.
